Introduction

This report presents a comprehensive analysis of historical stock market data spanning from 1962 to 2025. The primary objective is to uncover underlying trends, assess volatility patterns, and evaluate correlations among key financial metrics such as price, volume, and returns. Through a series of visualizations and statistical summaries, the report aims to offer clear insights into the long-term behavior of the asset in question, as well as short-term fluctuations and anomalies.

The analysis includes time series visualizations of prices, comparisons of monthly averages across multiple decades, rolling standard deviations, and a correlation matrix. These methods help reveal patterns in seasonality, momentum, and volatility. Additionally, descriptive statistics provide context for understanding the behavior of variables such as daily returns, average volume, and price adjustments due to dividends or splits.

The structure of the report is designed to progressively build insight—from raw observations to deeper interpretations—making it a useful reference for investors, analysts, or researchers looking to better understand price dynamics over time.

Chart Analysis

Stock Price Over Time

- The chart shows significant price volatility, with clear periods of both growth and corrections.
- Over the long term, the trend appears generally upward, despite several sharp downturns.

Price and Moving Averages

- Shorter moving averages react more quickly to price changes and may indicate potential entry or exit points.
- Crossovers between averages (e.g., MA50 crossing MA200) could signal trend reversals or confirmations.

Correlation Matrix

- The correlation between closing and adjusted closing prices is very high (0.97), indicating they move almost identically.
- Low or no correlation with trading volume suggests that volume does not significantly affect price movements.

Monthly Avg Price Subplots

- These plots may reveal seasonal or cyclical pricing behavior (e.g., recurring price patterns in certain months).
- Volatility and average price behavior can vary by month.

Monthly Avg Price Last 10 Years

- This chart highlights short- to medium-term trends and potential cyclical patterns over the most recent decade.

- It reveals visible month-to-month variations that may relate to macroeconomic cycles, earnings seasons, or calendar effects.
- Some months likely show higher average prices—possibly due to seasonal investor behavior or recurring events like Q1 rallies or year-end volatility.
- Emphasizes current behavior, offering clues for tactical or short-term strategy.

Monthly Avg Price Last 63 Years

- This broader timescale captures long-term structural changes in the stock market.
- We can observe major bull markets, corrections, and long-term economic cycles.
- The data likely shows periods of accelerated growth (e.g., dot-com boom, post-2008 recovery) and sharp declines (e.g., oil crises, financial crises).
- Overall, this chart supports the narrative of persistent long-term upward momentum, despite short-term turbulence.
- Shows how the asset evolved structurally over time.

Monthly Avg Price Years 1962–1982

- Lower price fluctuation, indicating a more stable and less volatile market.

Monthly Avg Price Years 1983–2003

- Noticeable increase in dynamics and more frequent price spikes.

Monthly Avg Price Years 2004-2024

- Significantly higher volatility, possibly due to speculative bubbles or financial crises.

Monthly Avg Price Years 2025

- Still early in the year—insufficient data for solid conclusions.

30 Day Rolling Standard Deviation of Adj Close Price

- Increasing standard deviation indicates higher risk and market uncertainty.
- Decreasing volatility points to market stabilization or consolidation phases.

Descriptive Statistics

- Open mean (18.53) and close mean (18.54) indicate relative daily price stability.
- Adjusted close mean (12.92) being lower suggests historical adjustments due to dividends, stock splits, etc.
- Standard deviation of adjusted close (16.79) reflects considerable price volatility.
- High standard deviation of volume (7957798.46) indicates substantial variability in trading activity. Some days experience significantly higher or lower trading volume than the average. This could be a sign of speculative trading, market reactions to news/events, or entry/exit of large institutional investors.
- The average daily return of 0.06% suggests modest, steady growth over time. While small in daily terms, such consistent returns can compound significantly over months or years.
- The average daily trading volume around 9.35 million shares reflects a highly liquid asset, frequently traded on the market. High liquidity typically allows for tighter bid-ask spreads and reduced transaction costs, which is favorable for both institutional and retail investors.
- Very high correlation (0.97) between close and adjusted close confirms that both metrics move together strongly.

Summary & Key Findings

This dataset provides a comprehensive view of historical stock performance. The key findings include:

- Consistent long-term upward trend in stock prices despite shorter-term volatility.
- Strong internal consistency, with close and adjusted close prices highly correlated.
- Rising market volatility in recent decades, especially post-2000.
- Stable average daily prices, with some fluctuations due to market events and structural adjustments.
- Useful indicators for technical analysis, such as moving averages and rolling standard deviations.

These insights form a solid foundation for deeper analysis of market behavior, forecasting, and investment strategy.

Recommendations

Based on the findings and visual interpretations, the following steps are recommended to extend this analysis and derive even more actionable intelligence:

1. **Seasonality Detection:** Analyze monthly price behavior using boxplots to identify consistent seasonal patterns (e.g., recurring Q1 or Q4 strength/weakness).
2. **Forecasting and Predictive Modeling:** Use time series models to forecast future price trends, with confidence intervals.
3. **Correlation with External Factors:** Compare the asset's behavior with macroeconomic indicators or index benchmarks (e.g., S&P 500, inflation, interest rates).
4. **Intraday Volume-Price Analysis:** Study how volume influences price on shorter intervals to uncover potential trading patterns.
5. **Event Impact Analysis:** Map significant price changes to historical geopolitical or economic events to measure impact sensitivity.
